Magnetic Core Loss Behavior At High Fields in Magnetic Materials

May 24th 2019

Background

- Soft Magnetic Composites (SMC's) are widely used in induction heating applications
- Having accurate data for magnetic core losses is critical for computer modelling in challenging applications
- Current methods for measuring core loss at higher frequencies have shown significant levels of variation trial to trial
- Current models for core loss do not agree with experimentally measured values over wide ranges of field strength and flux density

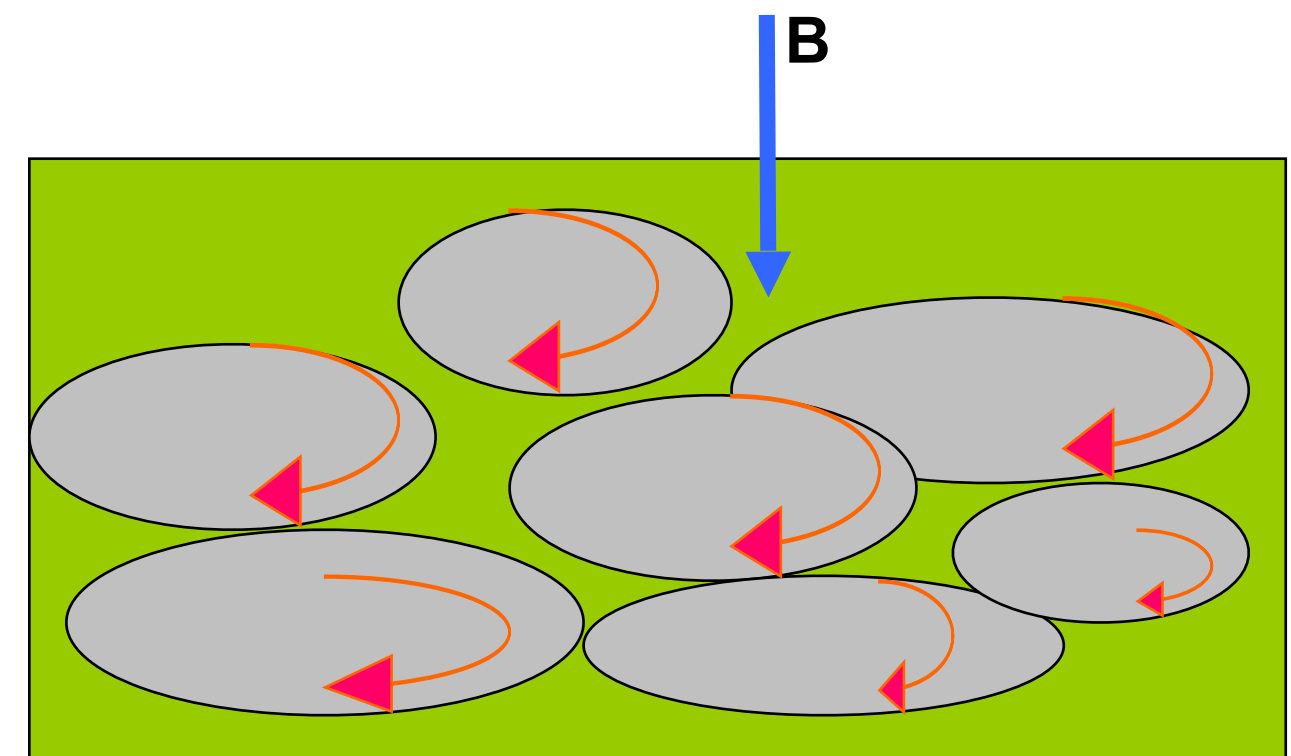

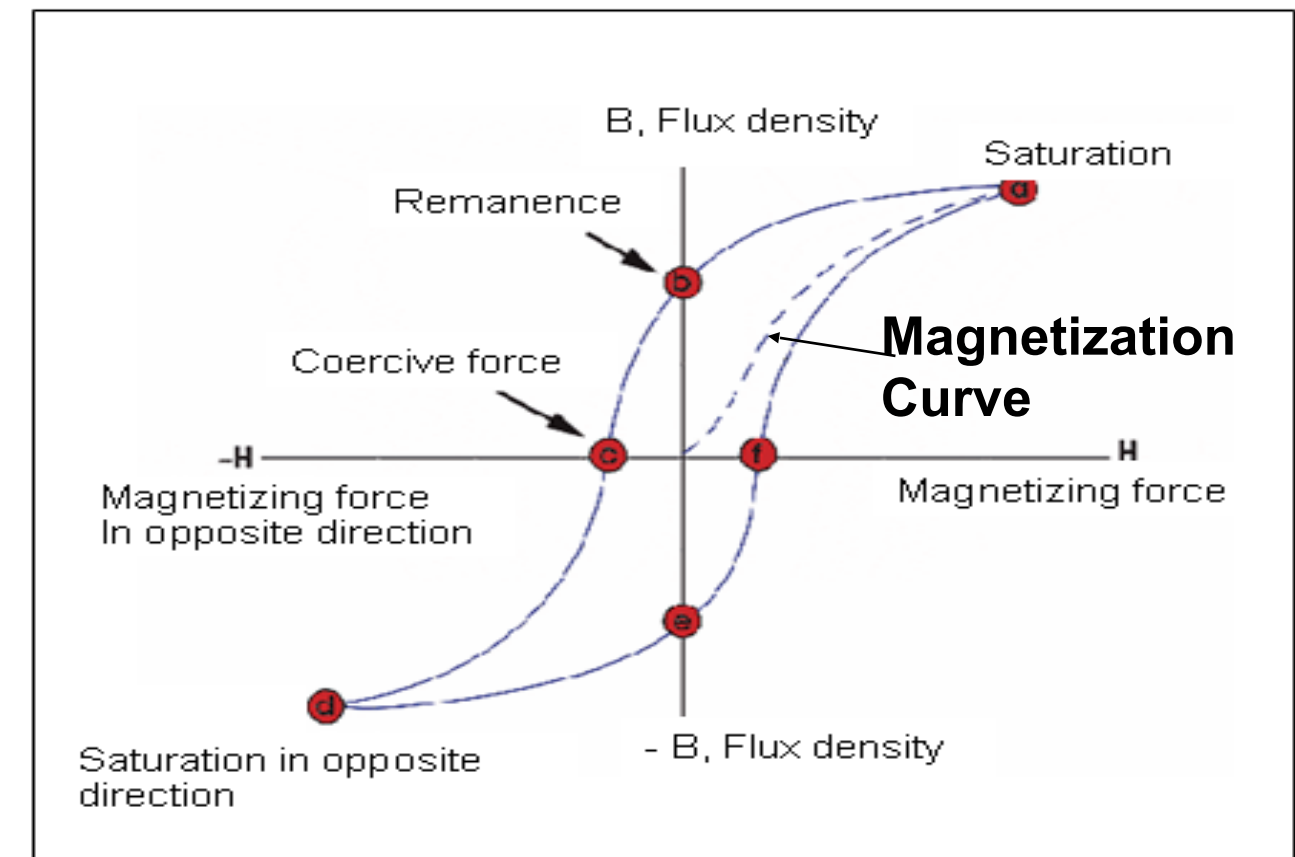

High Frequency Magnetic Core Losses

- Core Losses consist of 4 components
 - Hysteresis Loss
 - Eddy Currents in individual particles
 - Regional eddy current losses in a core
 - Global eddy current losses in the core
- Most common formula for approximation
 - Modified Steinmetz Equation -

$$P_v = k f^a B^b$$

- From a fundamental perspective, the formula should be (assuming good particle insulation) -

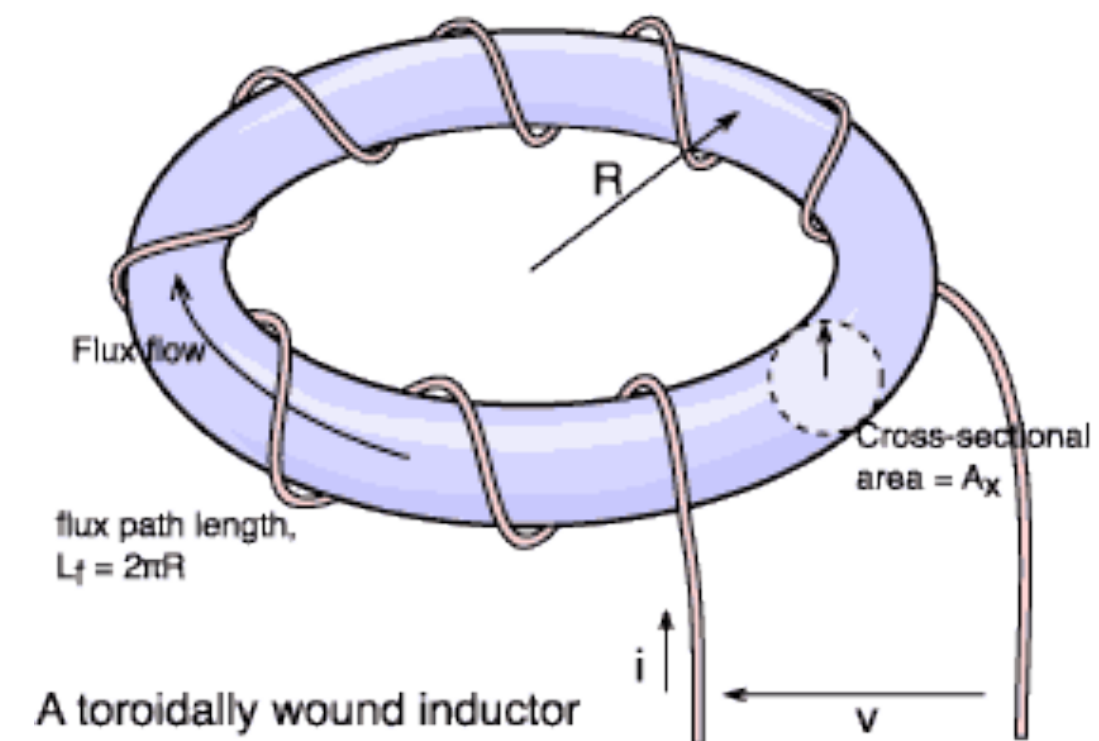

$$P_i = f \oint H dB + \frac{\pi^2 t^2 B^2 f^2}{6 \rho d}$$

Current Standard Core Loss Measurement Techniques

- Typically made via calorimetric method with adiabatic and uniform fluid temperature assumption or by calculating slope of initial heating curve
- Single point temperature measurement
- Torroidal core is typically wound with solid copper winding
- When turns number is reduced to reach higher flux densities, space factor for windings is low

Improved Measurement Method

- Multiple point thermocouple measurement
 - 3 in fluid
 - 1 on OD of insulation
 - 1 on Upper surface of vessel
 - 1 a few inches from vessel
- Use of litz wire to reduce winding loss
- Multiple turns in parallel to maximize space factor
- Short leads tightly coupled to limit leads effect
- Inverse calculation of magnetic loss based upon cooling curve analysis
- High boiling point liquid to avoid phase transformation

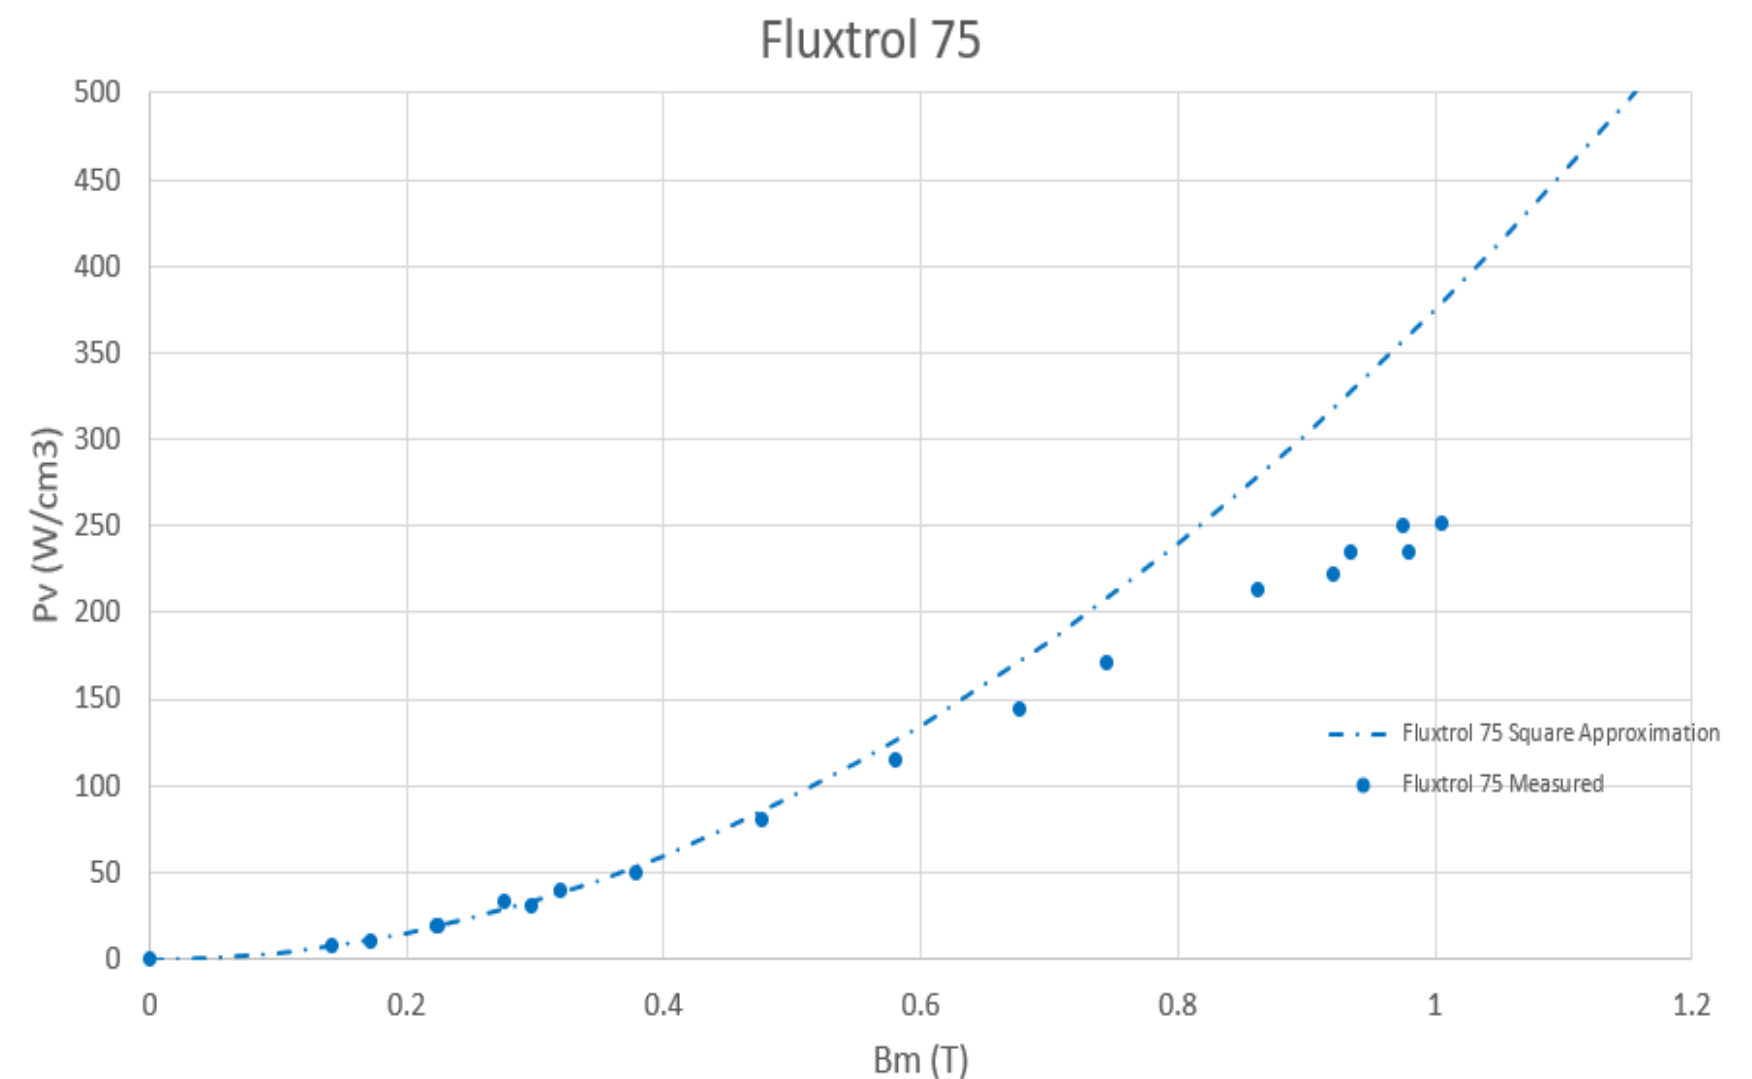

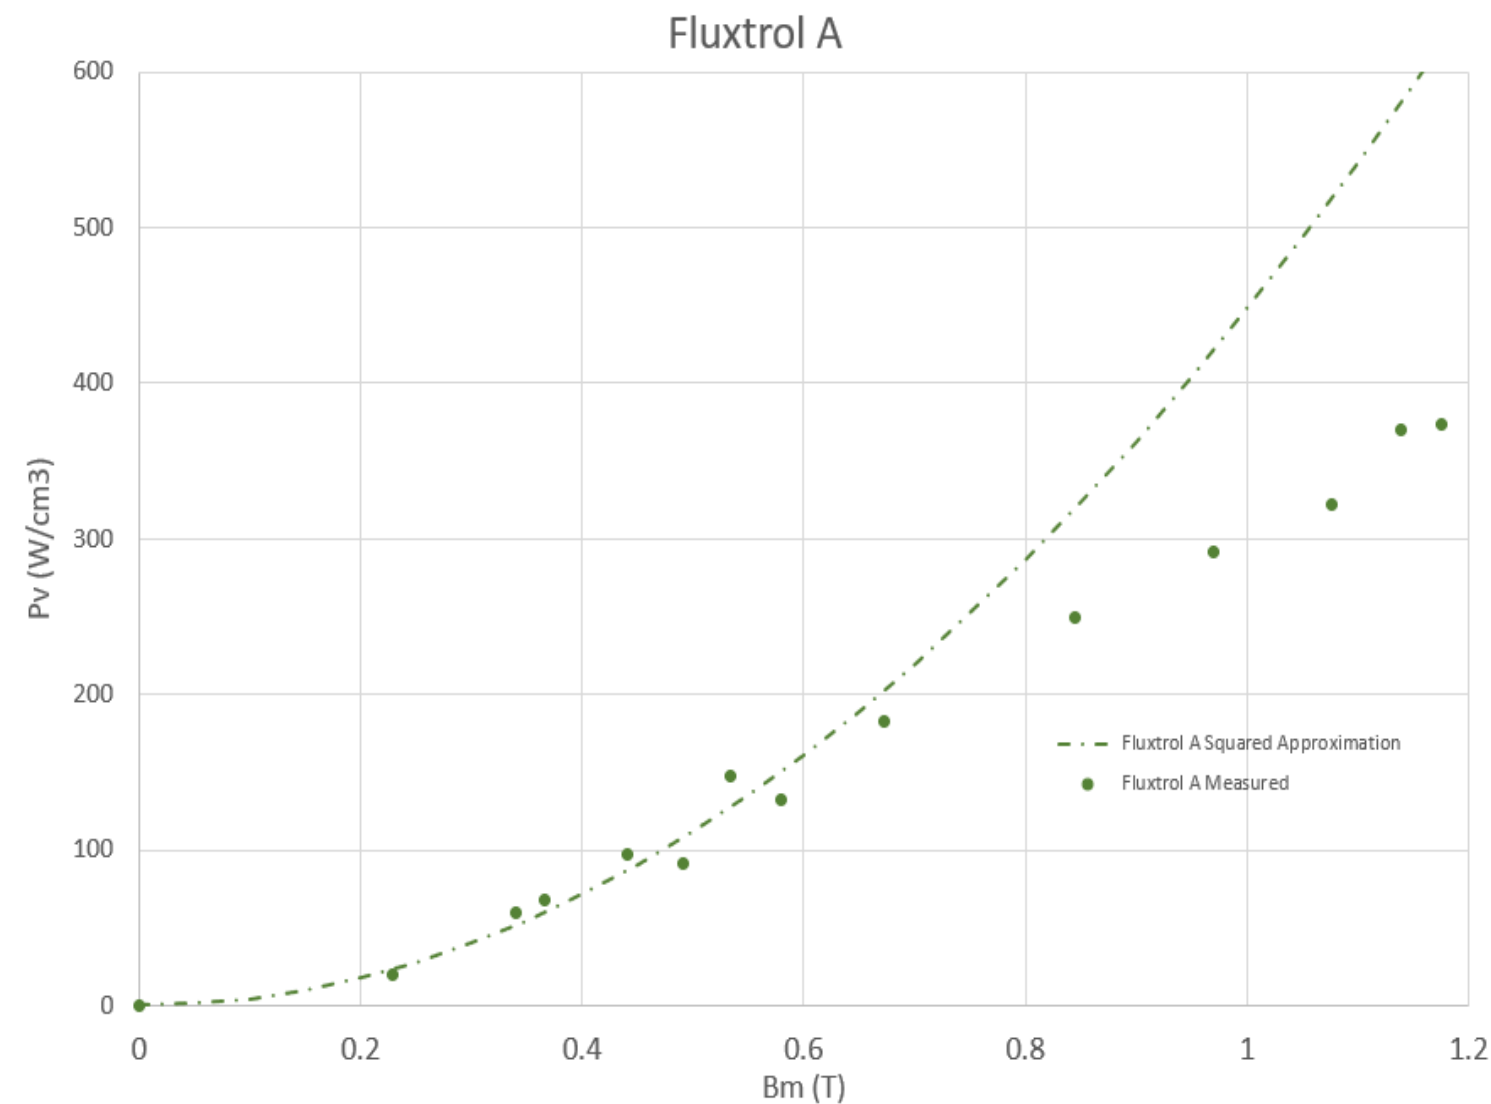

Distribution of Temperature in the System

- In this example, ΔT varied 2 X, which would lead to error of 100% between two different measurements using standard calorimetric calculation
- Using slope method, the variation would be similar. Also, in all 3 cases it is significantly less than the inversely calculated value due to thermal lag in the system

Loss Measurement for Fluxtrol A and Fluxtrol 75 at 150 kHz

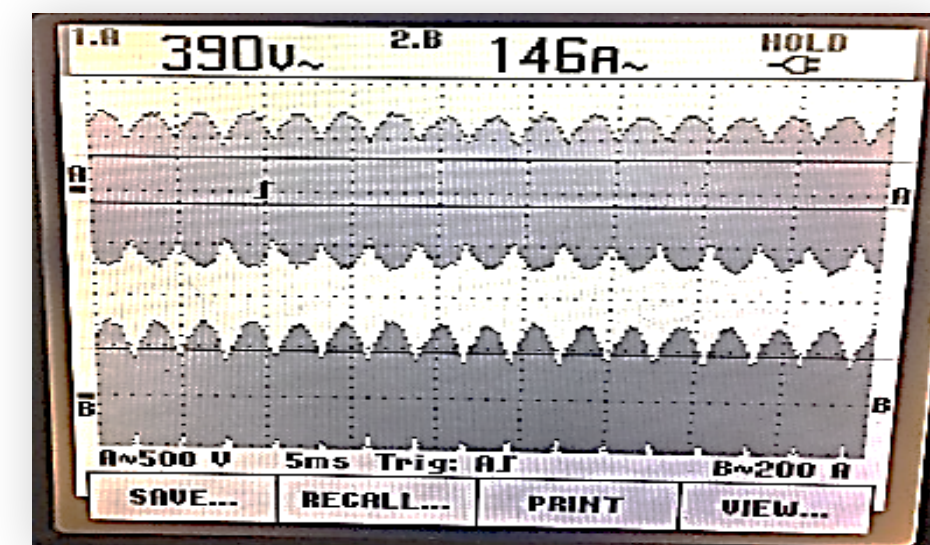

- At low magnetic flux densities, the losses can be approximated well by B^2
- As flux density increases, core losses rise at a much slower rate
- The declining rate of core losses is located where the magnetic permeability of the core is declining
- Same trend observed at multiple frequencies

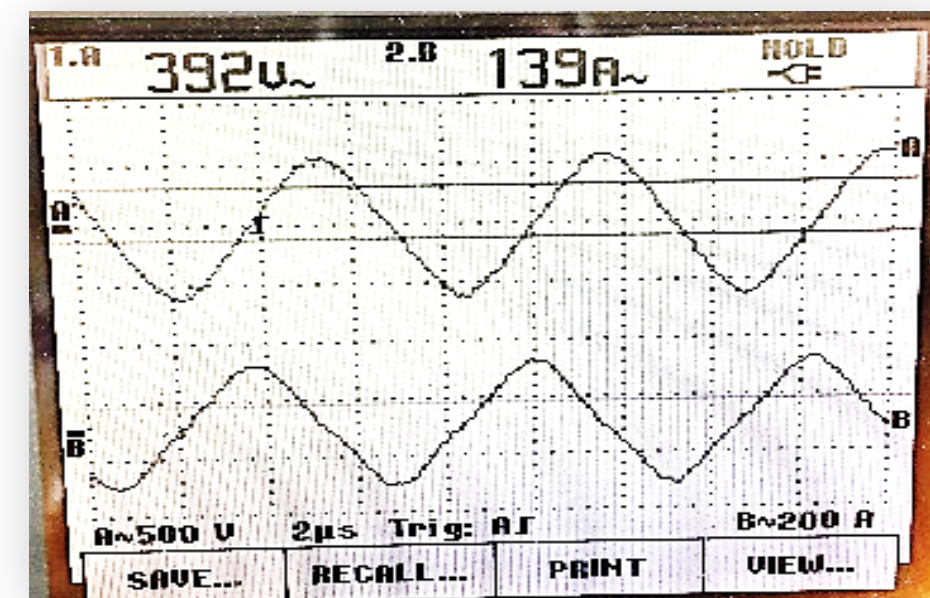

Notes About B_m Calculation for High Frequency Testing

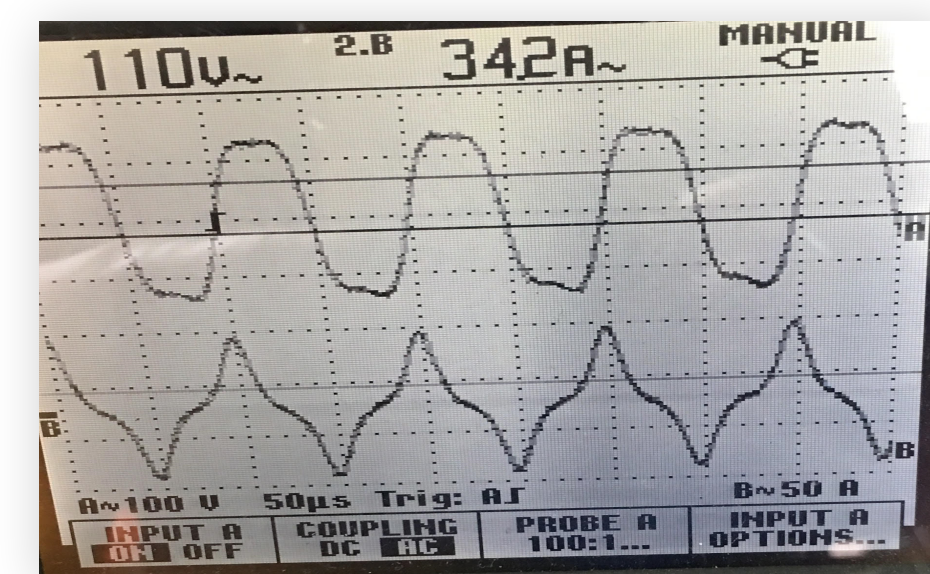

- Due to imperfect rectification, voltage/current values have a low frequency oscillation (typical for induction heating systems)
- As field levels increase, the magnitude of these oscillations increases
- Also, the shape of the current waveform goes from sinusoidal, to triangular, to strongly distorted as saturation is approached
- B_m calculated by multiplying the “Average” rms value by 1.414 to better match to simulation models, which assume constant rms signal

5 ms/div

2 μ s/div

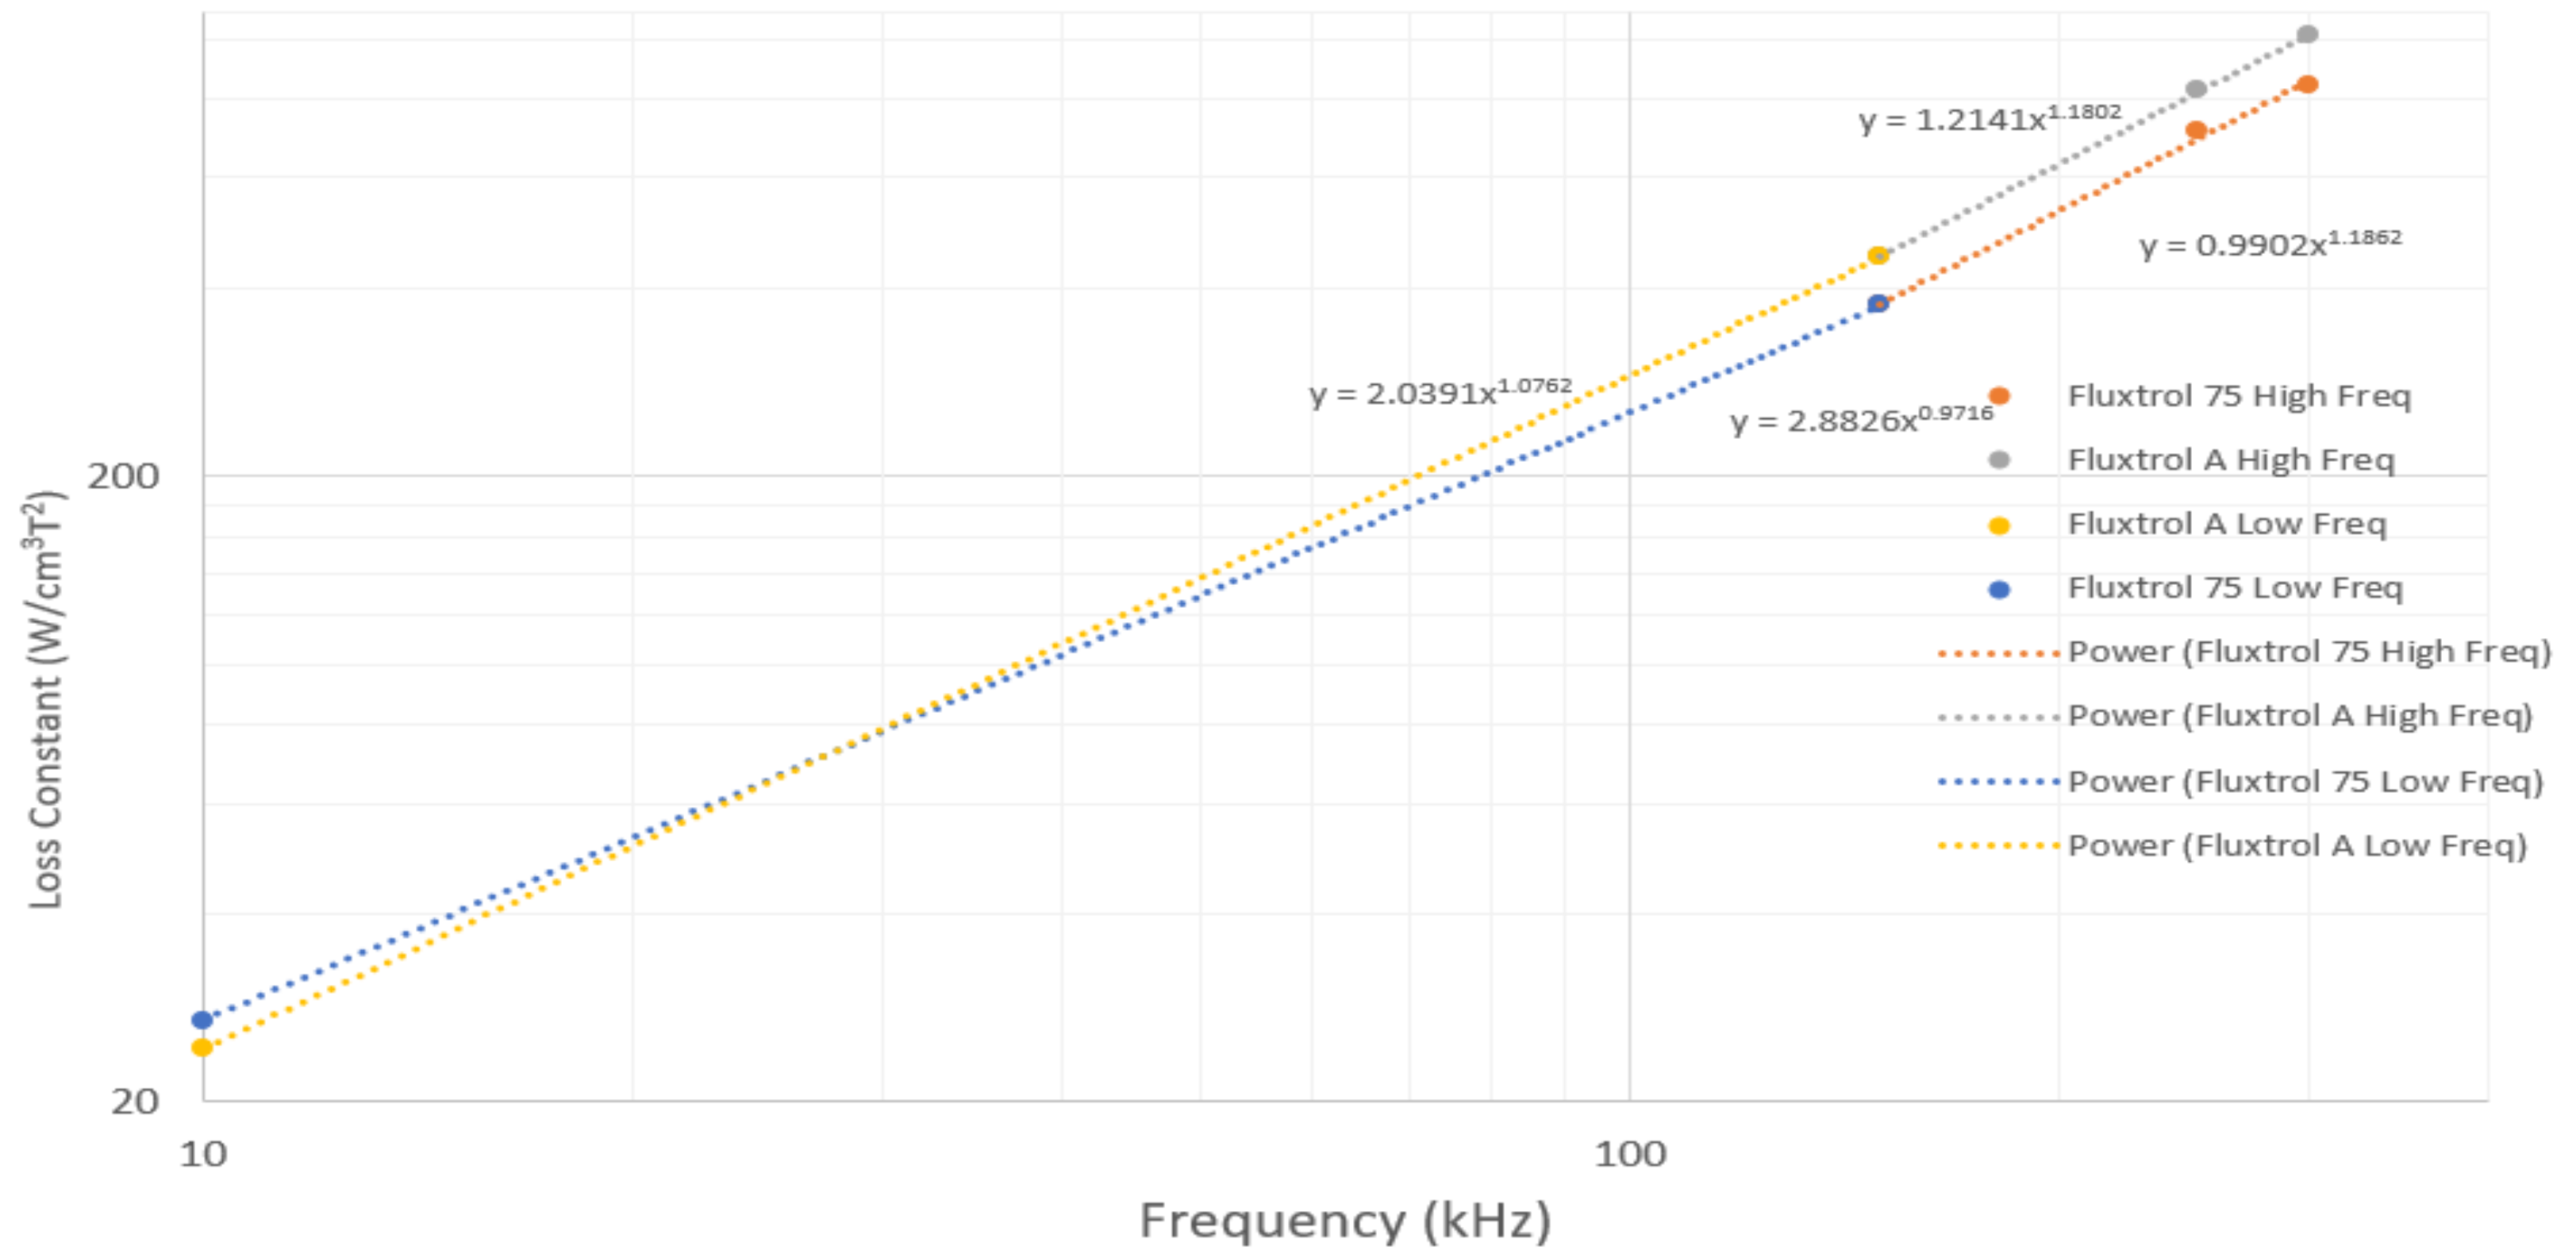

$\approx 1.2 \text{ T @ } 10 \text{ kHz}$

Effect of Frequency on “Low Field” Loss Constant

Comparison of Fluxtrol A and Fluxtrol 75 Loss Constants at Low Fields (<0.4T)

Conclusions

- Current Models being used for core loss description do not accurately depict real behavior
- Current models for measurement of core loss can be highly inaccurate in some cases
- A new loss measurement/calculation method has been proposed
- A new model for core losses needs to be created taking into account magnetic non-linearity and multiple loss sources with different dependencies

Future Work

- Work is currently underway to conduct these measurements for all of our materials over a wide range of frequencies and to update the database for our materials
- Work is underway in comparing the measurements at different frequencies and developing a mathematical function which can cover the full operating range of frequencies of our materials
- Should have separate constants for eddy current and hysteresis loss
- Function should account for magnetic saturation
 - Relationship should be similar, but different for eddy current and hysteresis
